## Solutions to Assignment \#1 <br> Two classic puzzles

The two questions below are similar to problems posed in the Middle Ages, and may well go back farther than that.

1. Three men robbed a gentleman of a vase, containing 24 ounces of balsam. Whilst running away they met in a wood with a glass-seller, of whom in a great hurry they purchased three vessels. On reaching a place of safety they wished to divide the booty, but they found that their vessels contained 5,11 , and 13 ounces respectively. How could they divide the balsam into equal portions? (Explain in detail, please!) [5]

Solution. Here is the solution given in the source [1] from which I got both problems:
Problems like this can be worked out only by trial: there are several solutions, of which one is as follows.

| The vessels can contain $\ldots . .$. | 24 oz | 13 oz | 11 oz. | 5 oz. |  |
| :--- | :--- | ---: | ---: | ---: | ---: |
| Their contents originally are | $24 \ldots$ | $13 \ldots$ | $11 \ldots$ | $5 \ldots$ |  |
| First, make their contents $\ldots$ | $0 \ldots$ | $8 \ldots$ | $11 \ldots$ | $5 \ldots$ |  |
| Second, | $"$ | $"$ | $\ldots$ | $16 \ldots$ | $8 \ldots$ |
| Third, | $"$ | $"$ | $\ldots$ | $3 \ldots$ | $8 \ldots$ |
| Fourth, | $"$ | $"$ | $\ldots$ | $3 \ldots$ | $8 \ldots$ |
| Fifth, | $"$ | $"$ | $\ldots$ | $3 \ldots$ | $8 \ldots$ |
| Sixth, | $"$ | $"$ | $\ldots$ | $8 \ldots$ | $8 \ldots$ |

A little effort should suffice to work out what pouring is done between containers at each step.
2. A game is played by two people, say $A$ and $B$. $A$ begins by mentioning some number not greater than six, $B$ may add to that any number not greater than six, $A$ may add to that again any number not greater than six, and so on. The winner is the first to reach fifty. Assuming both $A$ and $B$ play as well as possible, which one should win? Explain why in detail. [5]
Solution. Here is the solution given in the source [1] from which I got both problems:
$\ldots$ Obviously, if $A$ calls 43 , then whatever $B$ adds to that, $A$ can win next time. Similarly, if $A$ calls $36, B$ cannot prevent $A$ s calling 43 the next time. In this way it is clear that the key numbers are those forming the arithmetical progression $43,36,29,22,15,8,1$; and whoever plays first ought to win.

Similarly, if no number greater than $m$ may be added at any one time, and $n$ is the number to be called by the victor, then the key numbers will be those forming the arithmetical progression whose common difference is $m+1$ and whose smallest term is the remainder obtained by dividing $n$ by $m+1$.

Again, a little reflection and/or experimentation should suffice to convince you just how this solution works.
