Mathematics 2260H – Geometry I: Euclidean geometry TRENT UNIVERSITY, Winter 2014 Assignment #1

The Moulton plane Due on Monday, 21 September, 2015.

The *Moulton plane* is an example of a plane geometry that is not quite the familiar Euclidean plane. One way to define it is to start with the usual Cartesian coordinate plane and redefine the lines of slope m by redefining the operation of multiplication on the real numbers. The new operation of multiplication, which we will denote by \star , is defined in terms of the usual operation of multiplication as follows:

$$u \star v = \begin{cases} uv & \text{if } u \ge 0 \text{ or } v \ge 0 \text{ (or both)} \\ \frac{1}{2}uv & \text{if } u \le 0 \text{ and } v \le 0 \end{cases}$$

The points of the Moulton plane are just the points (x, y), for $x, y \in \mathbb{R}$, of the Cartesian plane. The lines of the Moulton plane include the vertical lines, x = a for $a \in \mathbb{R}$, of the Cartesian plane, plus all the "lines" satisfying the equation $y = m \star x + b$, where $m, b \in \mathbb{R}$. In practice, this means that all lines which are vertical, or horizontal, or have positive slope in the Cartesian plane are still lines of the Moulton plane. However, lines of negative slope are bent to make them only half as steep to the left of the y-axis:

- 1. Determine as fully you can which of Euclid's five Postulates, plus Postulates S and A from the textbook (pp. 39-41), are satisfied in the Moulton plane. [7]
- 2. Show that the Moulton plane does not satisfy Desargues' Theorem. [Look it up! We will see later that the Euclidean plane does satisfy this theorem.] [3]
