

## MATH 2260H Propositions I-30 to I-32,

wherein we meet the most popular  
equivalents of Postulate V.

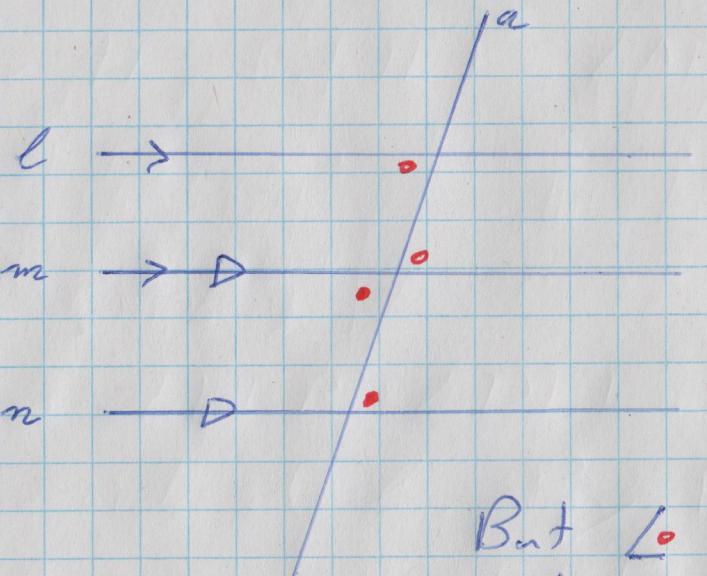

Recap:

Z-Thm.

$$\left. \begin{array}{c} \text{I-27} \\ \text{I-29} \end{array} \right\} \begin{array}{c} \cancel{\parallel} \\ \cancel{\not\parallel} \end{array} \Rightarrow \begin{array}{c} \cancel{\not\parallel} \\ \cancel{\parallel} \end{array} \quad \begin{array}{l} \text{Needs only Post. I-IV} \\ (\text{or S&A}) \end{array}$$

$$\begin{array}{c} \cancel{\not\parallel} \\ \cancel{\parallel} \end{array} \Rightarrow \begin{array}{c} \cancel{\parallel} \\ \cancel{\cancel{\parallel}} \end{array} \quad \text{Requires Post. V as well.}$$

Prop. I-30: Given three lines  $l, m, n$  such that  $l \parallel m$ , and  $m \parallel n$ , we also have  $l \parallel n$ . [Parallel" is a transitive relation.]

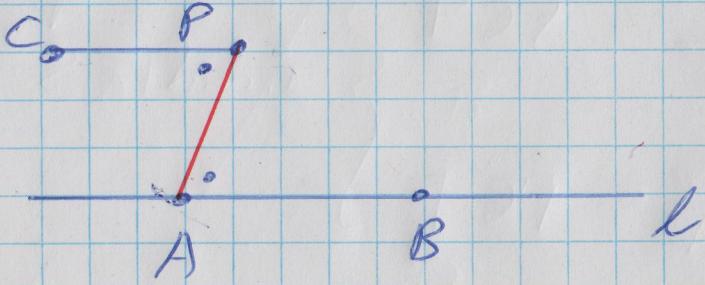

Proofs

Suppose  $a$  falls across all three of  $l, m$ , and  $n$ . Since  $l \parallel m$ ,  $a$  makes alternate interior angles  $\angle 1$  equal (I-29), & similarly  $m \parallel n$  means  $a$  makes alt. int. angles  $\angle 2$  equal.

But  $\angle 1 = \angle 2$  at line  $m$  by the Opposite Angle Thm. (I-15), so by I-27,  $l \parallel m \parallel n$ .

Prop I-31 Given a point  $P$  and a line  $l$ , there is a line  $m$  through  $P$  parallel to  $m$ . (2)

proof:

Pick a point  $A$  and another point  $B$  on  $l$ . Draw  $AP$ . Draw an angle  $\angle APC$  equal to  $\angle PAB$  at  $P$  (I-23) on the other side of  $PA$  from  $B$ .

Thus  $\angle APC = \angle PAB$ , so by I-27  $CP$  is  $\parallel$  to  $l$ .

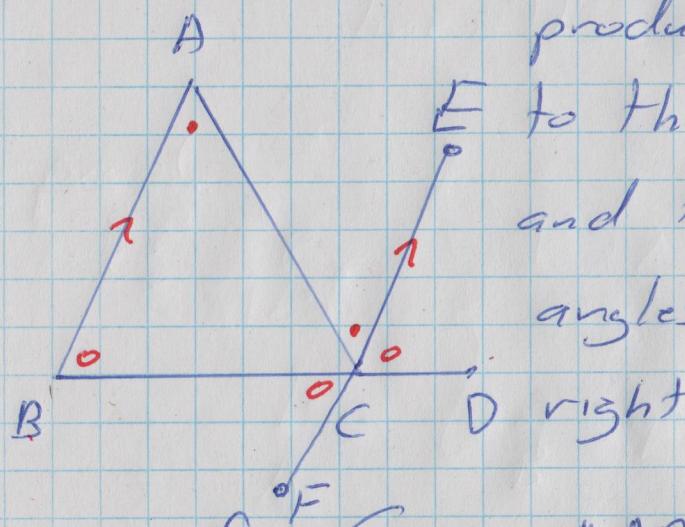

[The line  $m$  that extends  $CP$  is the line we need.]  $\parallel$

Note: This <sup>much</sup> only requires that we have Postulates I-IV (e&S).

Exercise: Showing that  $m$  is unique requires Post. V.

(3)

Prop. I-32: "For any triangle, if one of the sides is produced, then the external angle is equal to the sum of the two internal and opposite angles, and the sum of the three internal angles of the triangles is equal to two right angles."

proof: Given  $\triangle ABC$  "produce"  $BC$  past  $C$  to some point  $D$ .

To show: (1)  $\angle ACD = \angle ABC + \angle BAC$  ✓  
 (2)  $\angle ABC + \angle BCA + \angle BAC = 2b - \alpha$  ]

Use Prop. I-31 to draw a line  $CE$  through  $C$  which is parallel to  $AB$ .  $AC$  falls across  $AB$  and  $CE$ , so it makes alternate interior angles equal,  $\angle BAC = \angle ACE$ .  $BC$  falls across  $AB$  and  $CE$  so  $\angle ABC = \angle BCF$ . By Opposite Angles Thm. (I-15)

$\angle ECD = \angle BCF \Rightarrow \angle ECD = \angle ABC$ .  $\therefore \angle ACD = \angle ACE + \angle ECD = \angle BAC + \angle ABC$ .

Also,  $\angle ACD = \angle AEB + \angle ACE + \angle ECD = \angle BAE + \angle ACB + \angle BAC + \angle ABC$ .

(4)

In fact the assertions that, respectively,

the sum of the interior angles of a triangle is a straight angle,  
and

through a given point there is an unique ~~parallel~~ line  
parallel to a given line,

are each equivalent to Postulate IV, as is the  
hard direction (I-29) of the Z-theorem.
